

STEEL ROPES

 STALKANAT

CATALOG

The “STALKANAT” factory was founded in 1806. Today, the Private Joint-Stock Company “Stalkanat” is the largest enterprise in Ukraine that produces metal ware (wire, ropes, PC strands and metal fiber). The company employs over a thousand employees.

The company produces high-quality products in accordance with the national standards of Ukraine (DSTU), Russia (GOST), Germany (DIN), Great Britain (BS), USA (ASTM) and international standards (ISO, EN). State-of-the-art technologies implemented by the PJSC “STALKANAT” can satisfy the most stringent requirements of customers.

Our enterprise offers wide range of high-quality metal goods, and services as well as flexible payment terms. Currently, the main strategic directions of the PJSC “Stalkanat” development are related to satisfying customer expectations, improving the quality of products, renovating and modernizing our equipment, increasing productivity, and expanding the market share.

The main competitive advantages of the PJSC “Stalkanat” are as follows:

- a wide range of the metal ware products;
- a possibility to arrange delivery;
- high quality service;
- custom order/batch formation (upon customers request);
- flexible payment terms;
- long-term crediting of final consumers;
- precise and guaranteed terms of product delivery;
- technical assistance.

Main goals of the company - contribution in development of customers' business, providing them with wide range of products and associated services which meet their needs.

The company's products are exported to over 30 countries on all continents. Constant work at improvement of quality and reliability of supplied products aims to positions strengthen at local and foreign markets and product range expansion.

The main customers of the PJSC “Stalkanat” are both national and foreign enterprises of the coal-mining, oremining, gas-and-oil production industries, metallurgical industry, transport and agriculture machine-building, building industry, railway transport, energetics and a marine-economy complex.

The company has strict quality control of raw materials for ropes, rope wires and end products. The quality management system of the PJSC “Stalkanat” has been certified in compliance with the International Standard ISO-9001. All manufactured products comply with International standards and have the required quality certificates. For maritime shipping our company produces ropes in accordance with the Russian Marine Register of Shipping certificate and the certificate of the

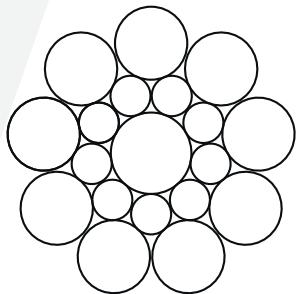

Shipping Register of Ukraine

Wire rope products of the PJSC “Stalkanat” - are available in wide range of steel wire ropes of various constructions. The base of any round rope is the strands that lay around central element - the core. The core, can be made from fiber (organic or synthetic), metal (arranged as a wire strand or as an independent wire rope), solid polymer or combination of materials. The strands of the rope consist of an assembly of wires of appropriate shape and dimensions laid helically in the same direction in one or more layers around a center.

The rope performance, its fatigue resistance, abrasive wear resistance and radial rigidity (crush resistance, for example, in case of multi-layer lay on drum) depend on the choice of strand and rope construction.

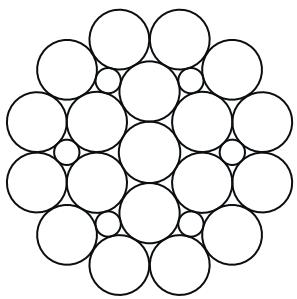

The main types of the steel rope strand constructions

S – Seale

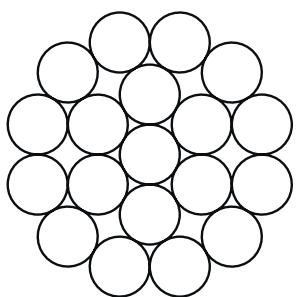

Parallel lay strand construction which contains of at least two layers with the same number of wires of different diameters laid in one operation and in the same direction.

F – Filler

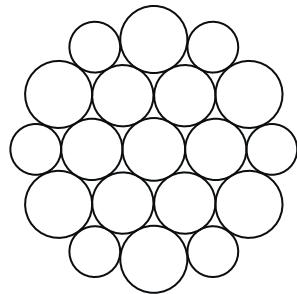

Parallel lay strand construction having an outer layer containing twice the number of wires than the inner layer, with filler wires laid in the interstices between the layers.

M

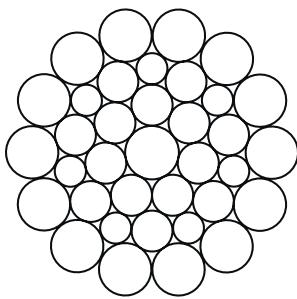

Constructions of the strand laid in several operations in which wires of superimposed layers cross one another and have a point contact.

W – Warrington

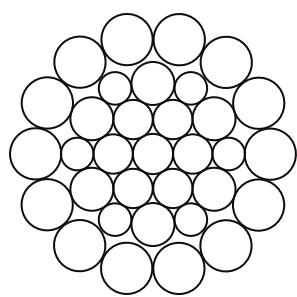

Parallel lay strand construction having an outer layer containing alternately large and small wires and twice the number of wires as the inner layer.

WS – Warrington-Seale

Parallel lay strand construction having three or more layers laid in one operation and formed from a combination of strand types Warrington and Seale.

N

Construction of a strand laid in several operations that has at least three layers of wires, the outer layer of which is laid onto the central construction of the parallel lay.

Increasing the number of wires and reducing their diameter allows to increase the fatigue resistance of the rope, but it reduces the abrasive wear resistance. Reducing the number of wires in the strands and increasing their diameter allows to increase the abrasive wear resistance, but it reduce the fatigue resistance of the rope. By choosing a six-strand cross-lay rope with a metal core, we get increased crush resistance during a multi-layer lay on the drum, unlike the multi-strand ropes, ropes with a fiber core or lang-lay ropes which are poorly resistant to radial loads. Ropes with polymer coating of a metal core can be used at wider angles of deviation than regular ropes.

That is why the choice of rope, as well as choice of any other equipment, should be made precisely and very carefully. It is necessary to take into account all the working conditions and parameters of the rope.

The main types of cores of steel ropes

The core is the most important element of the steel rope construction. It is the core that is responsible for preserving the shape and size of the rope cross section and it serves as a source of lubrication for the inner region of the rope strands during operation.

FC – fiber core

WC – steel core

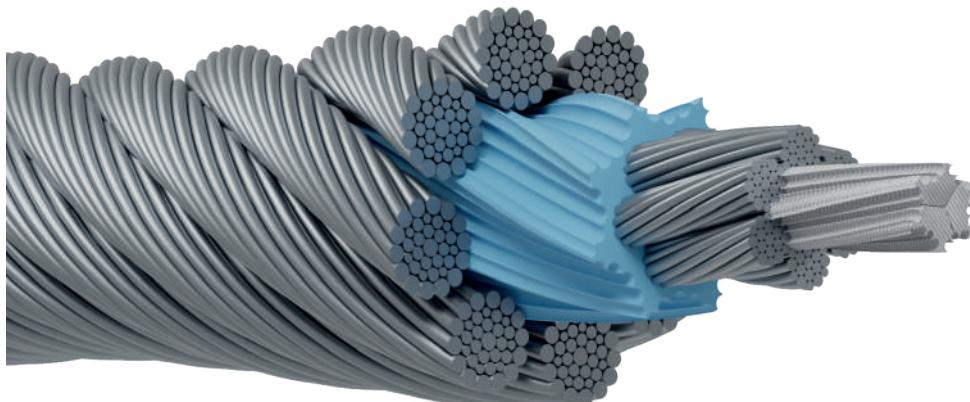

WSC – wire strand core

IWRC – independent wire rope core

EPIWRC – independent wire rope core covered with a polymer

Lay directions and types

sZ – right ordinary lay

sS – left ordinary lay

zZ – right lang lay

sS – left lang lay

aZ – right alternate lay

aS – left alternate lay

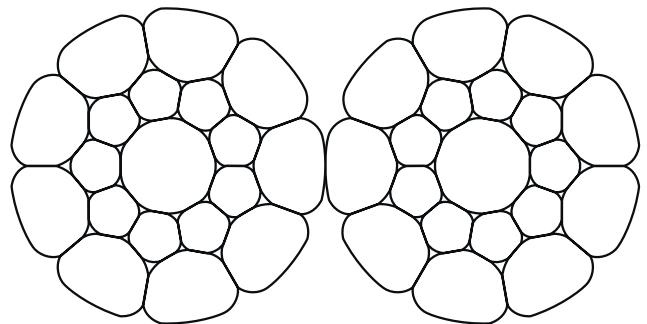

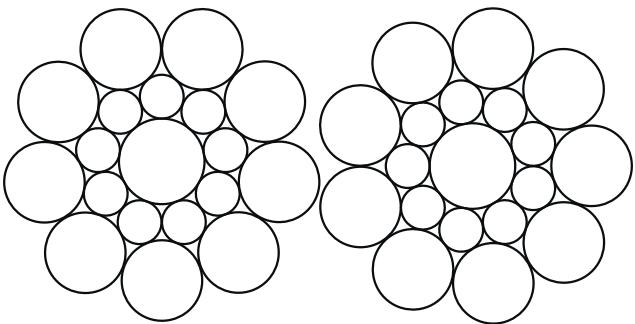

Manufacturing methods that extends steel wire rope lifespan

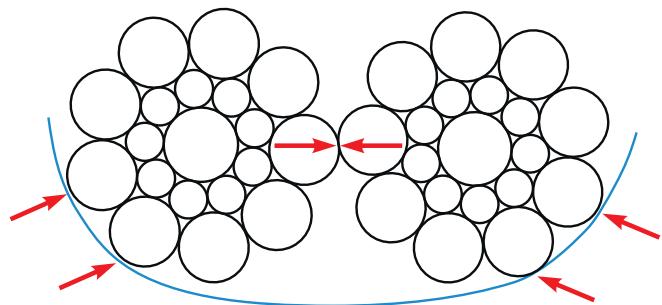

Ropes with compacted strands

One of the effective ways to extend steel wire rope lifespan is to make it with compacted strands. Before the strands are braid into a steel wire rope they are exposed to radiate swaging which cause wire deformation resulting into solidified structure and dense cross section. In the process of swaging, the outer diameter of the strand decreases, the metal cross-section area increases, since the voids between the wires inside the strand are filled. The surface of the strand becomes smoother.

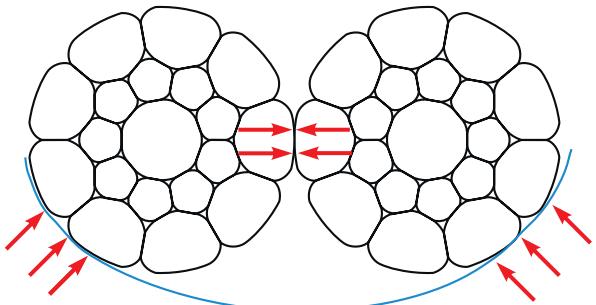

Improving of strand contact conditions

Locking out of wires is possible

Locking out of wires is excepted

Reducing of contact pressures

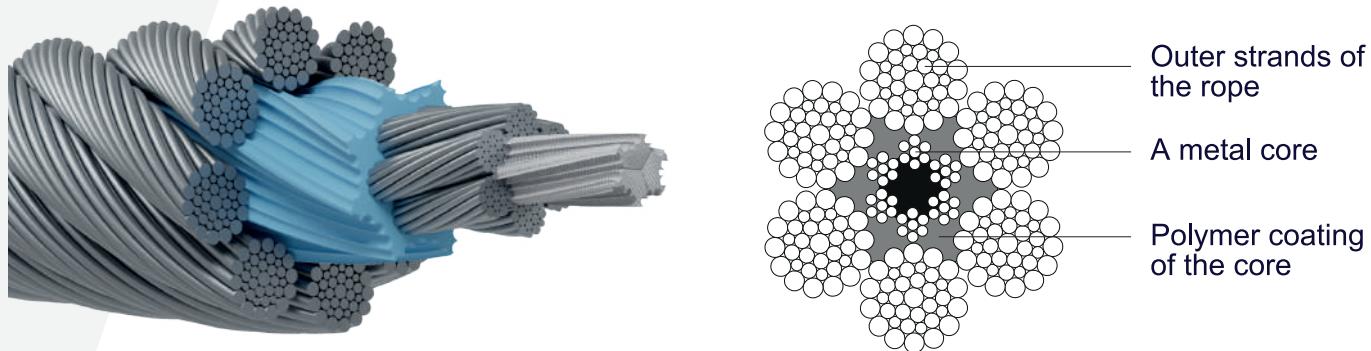

Advantages of compacted strands:

- Rope with swaged strands have higher tensile strength comparing to regular ropes of all diameters.
- Wires in swaged strands have smother contact with each other comparing to round wires of regular strands.
- Smooth surface of swaged strands provides better contact with surface of pulleys and drums resulting in higher endurance of equipment and of the rope itself.
- Ropes with swaged strands have high abrasive wear and flexural fatigue resistance.
- Contact between outer strands and contact between layers of rope on the drum are far better comparing to regular round strand ropes.

A core with polymer coating

Steel wire rope with polymer coated metal core consists of layer of strand braided around metal core which is covered in polymer using extrusion method. Polymer coating drastically reduces possible glide between rope elements and prevents geometrical change of the rope.

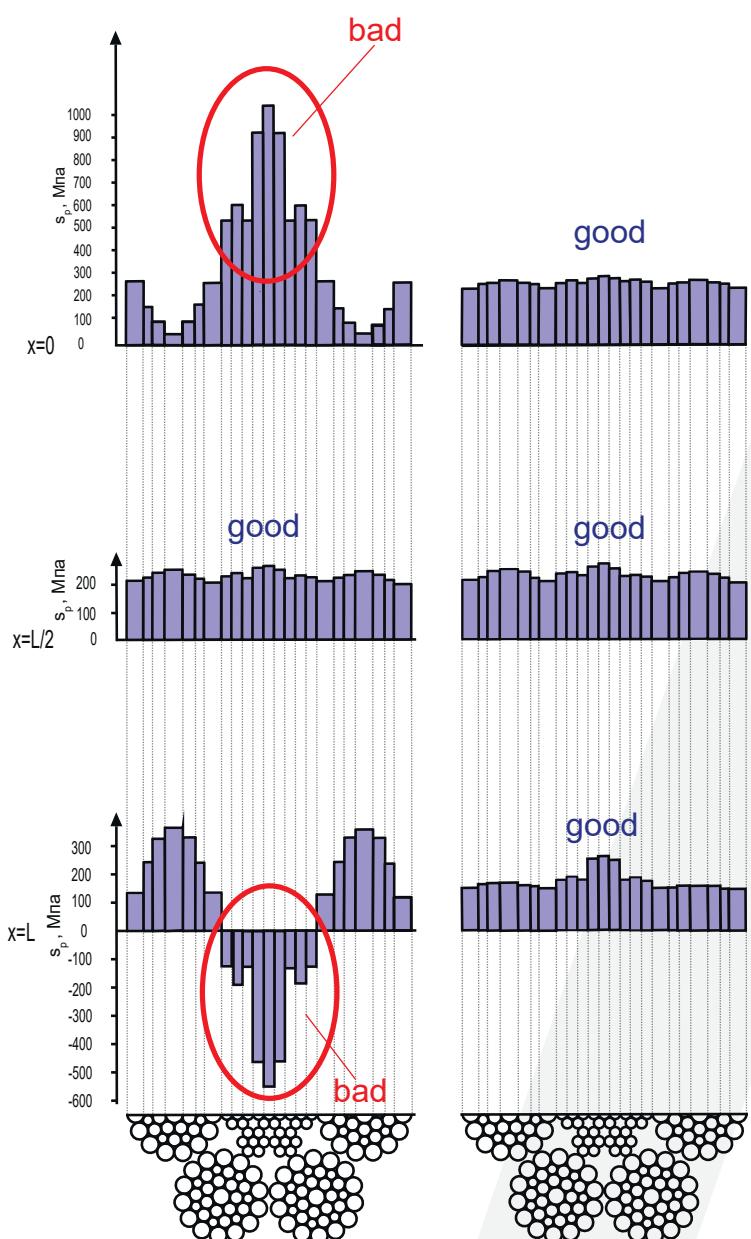

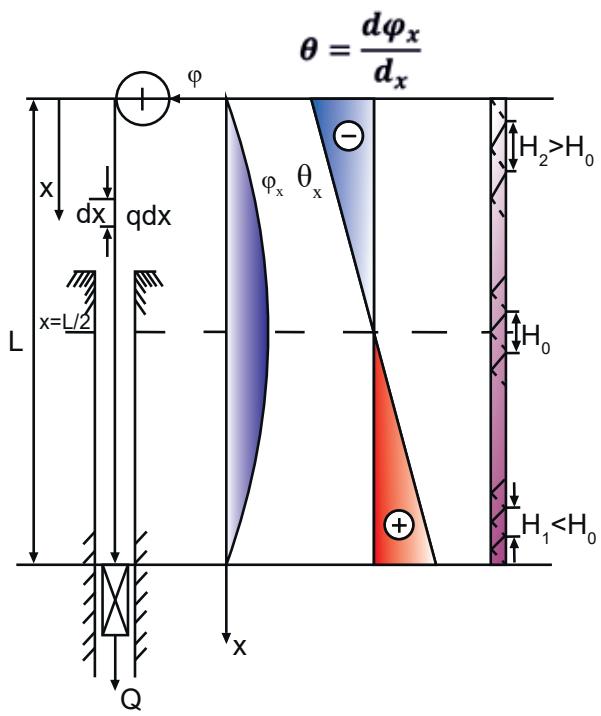

Plastic covering has the following purposes:

- Creation of physical bound that fixates positions of certain components of steel wire rope and provides their required shift.
- Reducing of internal corrosion caused by pollutants due to higher hermetic state of the rope.
- Filling of gaps between outer strands and core to eliminate wear.
- Special type polymer is created to be used between -35 and +90 without dimensional change or breaks.
- Stabilizing effect of plastic coating is seen the most during influence of lateral thrust, rotation, caused by wide deviation angle on pulleys, influence of impact stress.

Adapted steel ropes

The essence of this solution is to pre-design and manufacture a hoist rope with geometrical parameters as close as possible to the parameters that the rope acquires in a vertical hanging due to gravitational rotation. For this, strands are braided with variable lay lengths along the rope. The logic of variation of the lay lengths depends on the type and parameters of the sinking equipment, for which this rope is proposed. Therefore, we call such hoist ropes adapted. This processing technique, developed under the guidance of Professor V. Malinovsky. (Patent No. 85078) allows to reduce the gravitational rotation of the rope in the mine shaft and leads to a more uniform distribution of stresses among the wires in the strands of the rope, which allows to increase in fatigue strength and service life of mine hoist ropes. The adapted ropes are recommended for use in the mines with depth (the length of the rope in a vertical hanging line) of more than 1000 m.

The hoist rope rotation scheme in a vertical shaft and normal stress diagrams for a standard rope Ø 42 mm according to Std. EN 12385-4 6x36WS-IWRC (GOST 7669-80) and a rope of the same construction, but the adapted one.

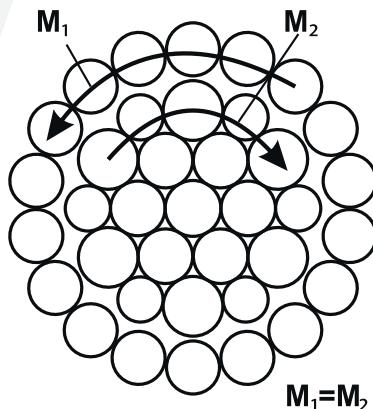

- a) hoisting diagram
- b) diagram of cross-section turn angles
- c) torsion strain of the rope
- d) equilibrium state of the rope
- e) diagram of the normal stresses in a standard rope
- f) diagram of the normal stresses in the adapted rope

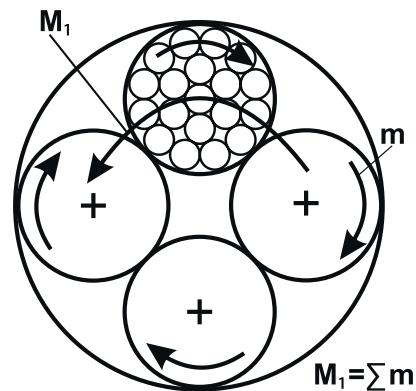

Rotation-resistant ropes and low torque (low rotation) ropes

Rotation-resistant ropes are ropes (mostly multilayer ones) in which balance of the torques is achieved. There are two constructive ways to achieve balance conditions for steel ropes:

1st way – due to contra-lay of the rope layers

2nd way – due to ordinary lay in a ropes with up to 4 strands

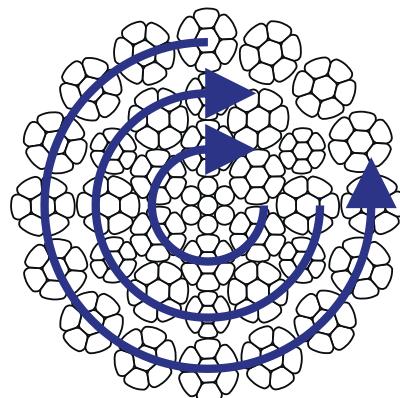

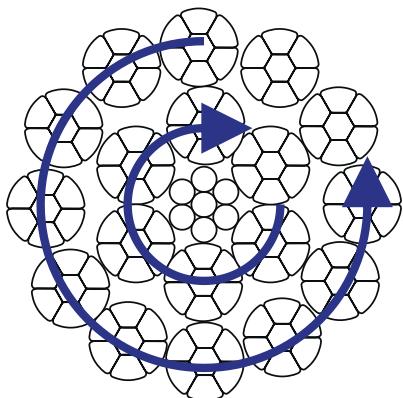

Multi-strand ropes with at least 3 layers of strands laid around the core having at least 15 strands in outer layer can be considered rotation-resistant ones.

Moreover, the outer strands should have the opposite direction of the lay, comparing to the strands of the inner layers of the rope. Such ropes have a very low torque or do not have it at all in a certain range of loads. They may be used with one free end, with or without a swivel.

Low-torque (low-rotation) ropes include ropes with more than ten outer strands and having at least two layers of the strands laid around the core with an outer layer of strands laid in the opposite direction comparing to inner layers. They have a significant torsional resistance. But in order to have a stable operation, they are not recommended to be used with one free end and with a swivel.

Special approach to handling of such ropes is required due to complexity of their construction.

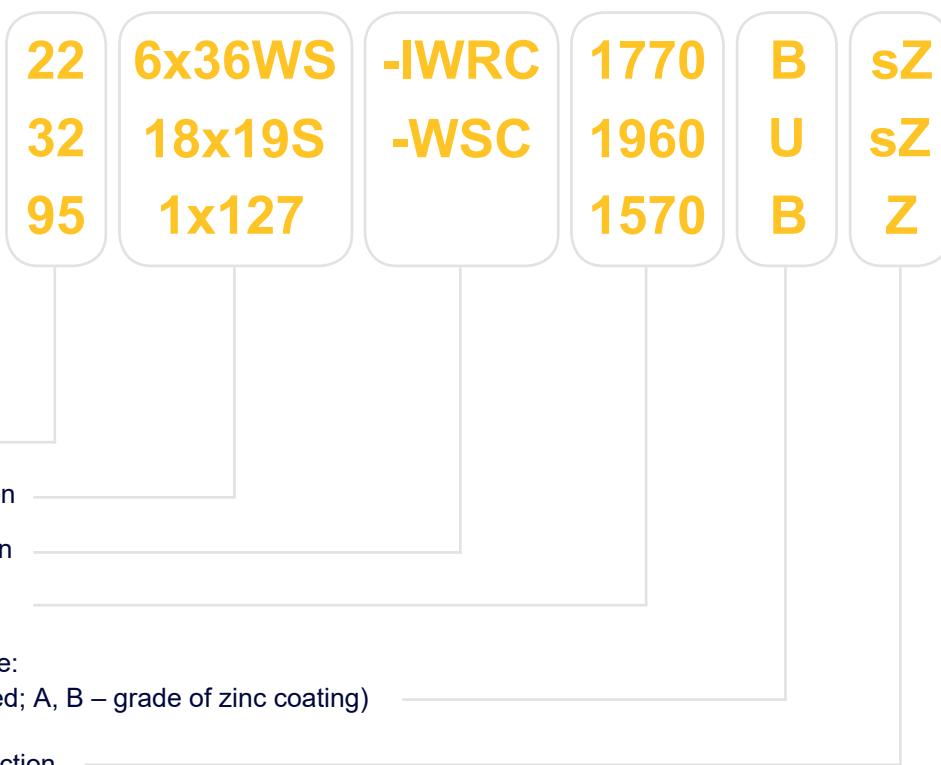

In the single-layer low-strand, non-rotating, ordinary-lay ropes, there is another principle of torque balancing. At certain lay parameters of both strands and rope equality of torques is reached.

Low-strand ropes have a small contact surface, which reduces their endurance while working on blocks and drums, but this problem is solved by the use of compacted strands. Four-strand ropes are not recommended for use with a swivel.

The low-strand ropes are much simpler than the multi-strand non-rotating ropes and they have a high structural stability. Therefore their application in certain cases is rather effective.

Steel rope diameter

CORRECT MEASUREMENT

INCORRECT MEASUREMENT

Tolerance to the rope diameter according to
EN 12385-4 requirements

Nominal diameter of the rope, mm	Limit deviation from the tope nominal diameter, %
From 2 to < 4	+8 0
From 4 to < 6	+7 0
From 6 to < 8	+6 0
8 and more	+5 0

**The following codes for rope lubricants are used at
the “STALKANAT”**

Lubricant code	Fibre core	Steel core		Rope strands	Rope
		strand	as a whole		
S (A)	without lubricant				
A 0	-	lubricated	without lubricant	without lubricant	without lubricant
A 1	lubricated	lubricated	without lubricant	lubricated	without lubricant
A 2	lubricated	lubricated	lubricated	lubricated	lubricated
B 2	lubricated	lubricated	lubricated	lubricated	lubricated with wiping *

* Note: “lubricated with wiping” means that the rope is lubricated in a bath by immersing it with further wiping off the extra lubricant by means of a rubber technical tube (Std. GOST 5496-78 or Specs. TY 38105881-85).

Code “A0’ is used for the ropes with a metal core only, since lubricant is pressed out from a core while laying the rope, after that the rope looks like lubricated. Other ways of lubrication are possible, at customer’s request.

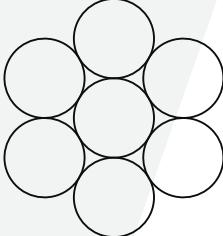

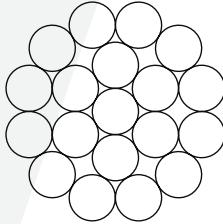

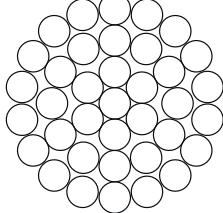

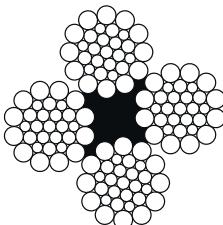

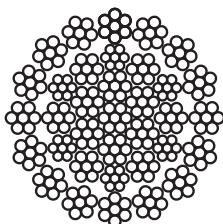

Minimal required information for rope order

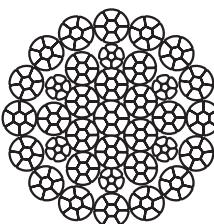

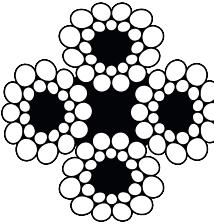

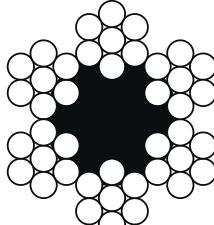

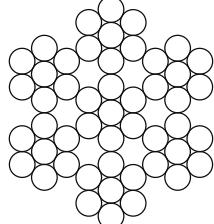

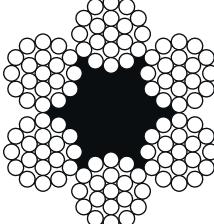

- Rope designation
- Nominal diameter of the rope
- Rope construction
- Strand compaction
- Core material and necessity in its covering with polymer materials
- Tensile Strength
- Type of coating (Bright, Galvanized)
- Lay direction and type
- Regulatory document (standard)
- Minimum breaking force
- Lubrication code
- Nominal length
- Requirements to tare and packing
- Required certificates (Maritime Register, API, etc.)

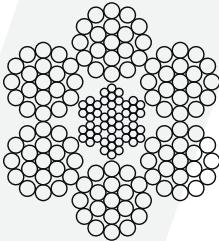

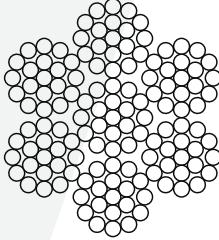

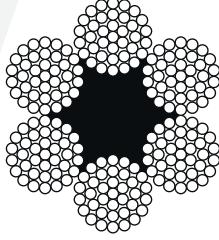

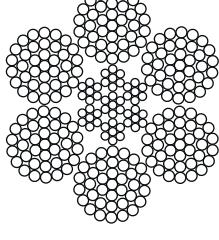

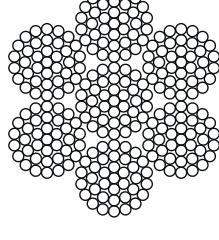

In case of order on mine ropes or presence of special requirements, additional information will be required. Therefore, it is recommended to consult with our specialists before ordering. This will allow you to select or develop a rope for specific equipment and specific operating conditions, as well as to get advice on the specificity of use, installation and operation of ropes.

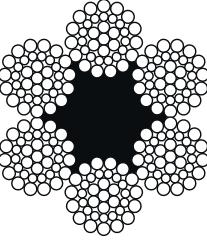

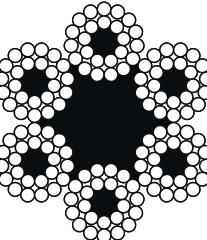

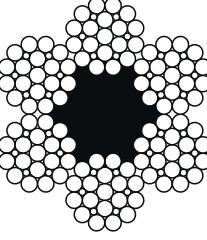

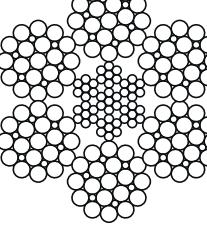

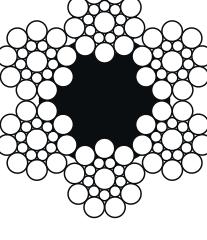

On customer request, the ropes can be produced with other intermediate sizes and tensile strength. The values of breaking forces of the ropes tensile strength of which are not listed in the table, will be increased by approximately 6% for every 100 N/mm².

Advice for transportation, storage, installation and operation of steel ropes

Transportation

1. Ropes are transported by all types of transport in covered and open vehicles in accordance with the rules for the carriage of goods applicable for this type of transport. Placement and securing of cargo during rail transportation is carried out in accordance with the Rules for loading and securing cargo.

2. Ropes are supplied on drums or in coils depending on the diameter, length of the rope and on customer's requirements.

3. Upon the rope delivery to the place of storage or installation, the drum must be removed from the vehicle by means of load-lifting mechanisms in a way to prevent damage of the rope and drum. It is prohibited to throw the drum with the rope off the vehicle or to remove it in ways that may result in its damage or disruption of the layer of conservation grease. During such operation, the rope itself should not come into contact with any part of the lifting mechanism, such as a crane hook or forklift fork. It is preferable to use textile slings.

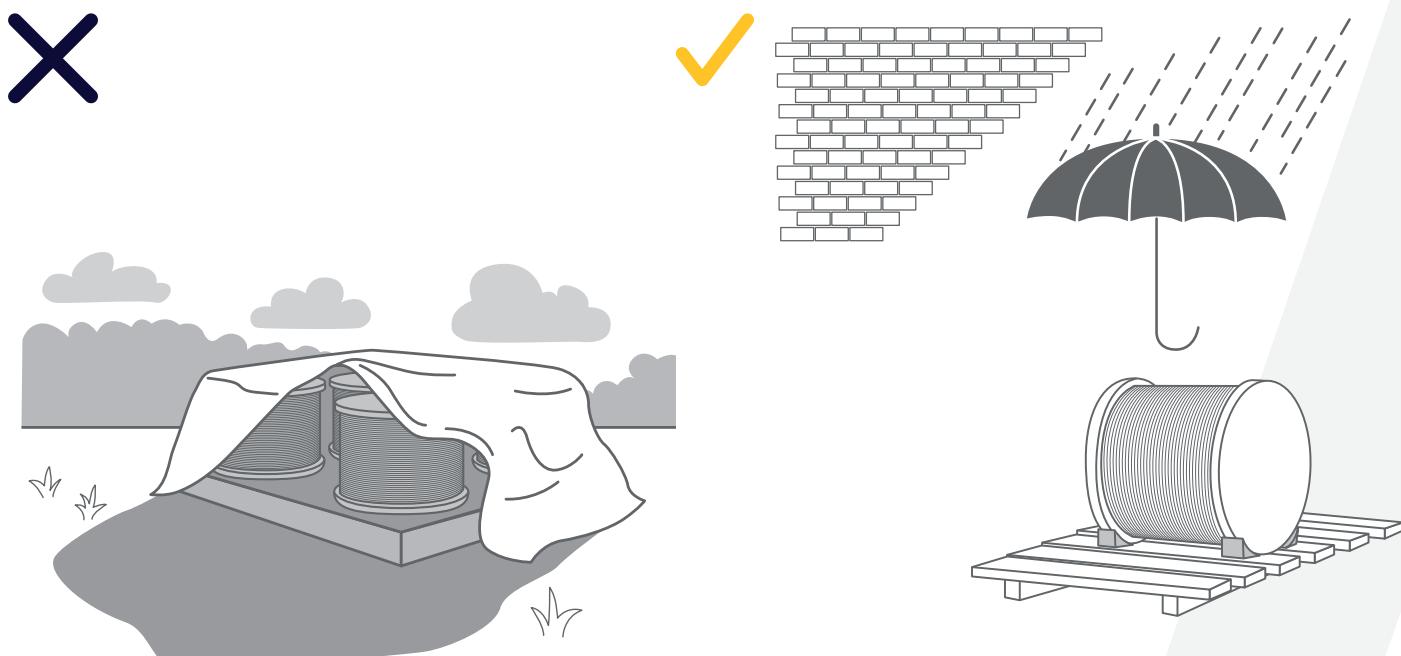

Rope acceptance procedure

1. Immediately after delivery, condition of the rope, compliance with the quality certificate and order requirements should be inspected. Rope marking should be checked to ensure that it is clear and complies with the quality certificate. If damage of the rope or its packaging is detected, it must be recorded on the acceptance statement.
2. Manufacturer Quality certificate of the rope should be stored in a safe place, for example, with the crane operating manual for identifying the rope during periodic comprehensive inspections of the rope. The owner has no right to use the rope for lifting without the quality certificate.

Storage of ropes

1. The ropes received for storage are subject to immediate inspection, all parts that lack greasing after transportation and unloading should be lubricated with special rope lubricant.
In this case, the lubricant must be compatible with the one used by manufacturer.
2. When unloading and store-keeping, do not violate the integrity of the drum, packaging, lubrication and avoid mechanical damage to the steel rope.
3. Rope storage should be carried out in clean, dry and ventilated facilities (where temperature and humidity fluctuations do not significantly differ from those in the open air in macroclimatic regions with a temperate and cold climate in any type of atmosphere), in conditions that exclude effect of atmospheric precipitation, as well as chemical vapors, steam, saline or any other corrosive substances. Failure to comply with this condition may lead to contamination of the rope with pollutants that may cause corrosion even before its commissioning.

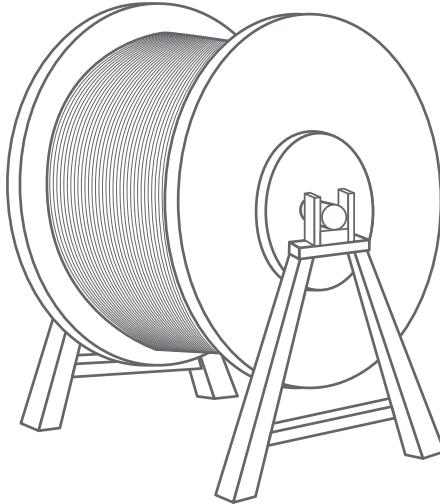

4. Make sure of keeping a steel rope away from heat sources that can result in thinning of the lubricant layer and its runoff from the rope.
5. When the consumer is storing a rope on a drum, the axis of the drum must be parallel to the floor where the drum has been installed.

The drum should be positioned so that the space under it is ventilated. Do not stack drums directly on the ground. They should be installed on special flooring, liner-bars or racks. Preferably, the drum should rest on an A-frame or a support, mounted on the floor, that is capable of safely supporting the total weight of the rope and drum.

6. If the rope is supplied on a transport drum, then during the long periods of storage, especially in a warm environment, the drum must be shifted periodically to prevent lubricant from non-uniform distribution in the rope. It is also necessary to periodically (at least once every 6 months) inspect ropes outer layer and lubricate it with compatible lubricant.

7. When decommissioning a rope for storage and further use, it is necessary to place it on the drum after thorough cleaning and lubrication. Used rope should be given the same attention as a new rope while storing.

8. Make sure that the conditions of storage and protection of ropes completely exclude any possibility of their damage at the time of placement into the warehouse, during storage or removal from the warehouse. Neglecting these recommendations can lead to a loss of strength of the rope and a decrease in its operating time or even its complete unsuitability for operation.

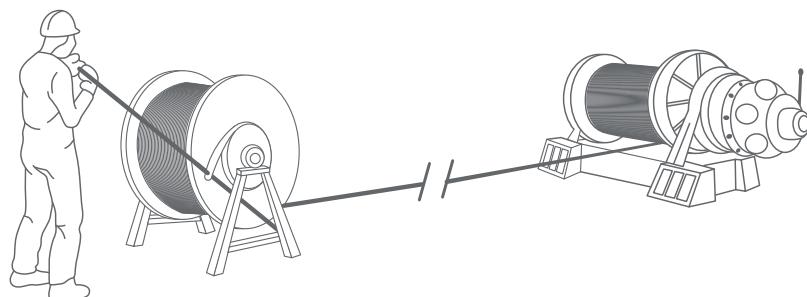

Rope unwinding

1. To unreel a rope that was delivered in a coil, it is necessary to put it on the floor vertically, after that roll it in a straight line by holding the free end of the rope avoiding contamination of the rope with dust, sand, moisture or other harmful materials.

2. It is unacceptable to unreel the rope from a fixedly laid flat coil, as this will lead to rope twisting and the formation of loops in it.

3. The coil can be placed on a turntable, which will allow unreeling the rope by pulling on its outer end.

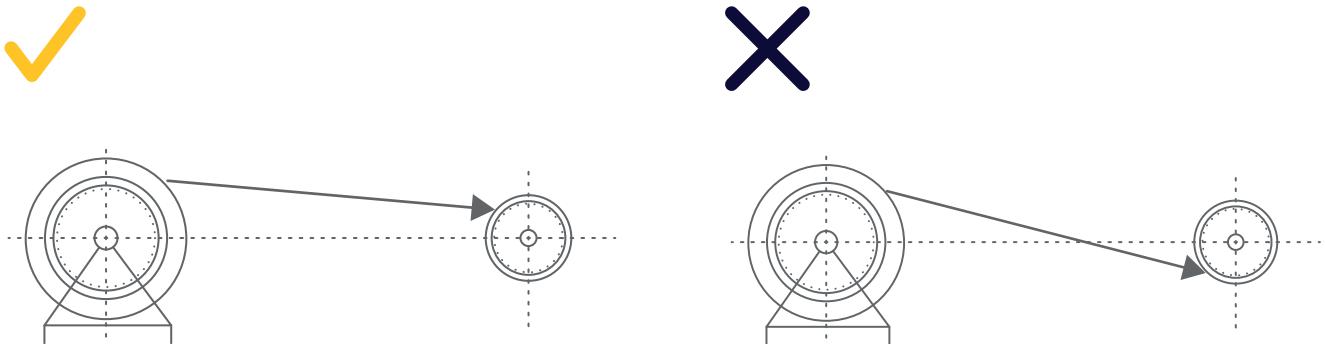

4. To unreel the ropes delivered on a transport reel, special spooling devices should be used to ensure the horizontal location of the reel axis and which are equipped with a braking device to create a rope tension in order to avoid loops and creases. Rope unreeling without using a braking device, as well as without creation of tension by braking the rope itself, is prohibited.

5. Installation of a transport reel into the spooling device is carried out by means of a shaft with sufficient strength, which is passed through the axial opening of the reel.

6. The transport reel should be positioned so that the deviation angle during unreeling be minimized (1.5° max). The distance between the reels (or between the reel and the guide pulley) must be at least 300 diameters of the rope. The diameter of the neck of the transport reel must be at least 15 nominal diameters of the rope. Failure to comply with this condition may cause damage to the rope when unreeling it.

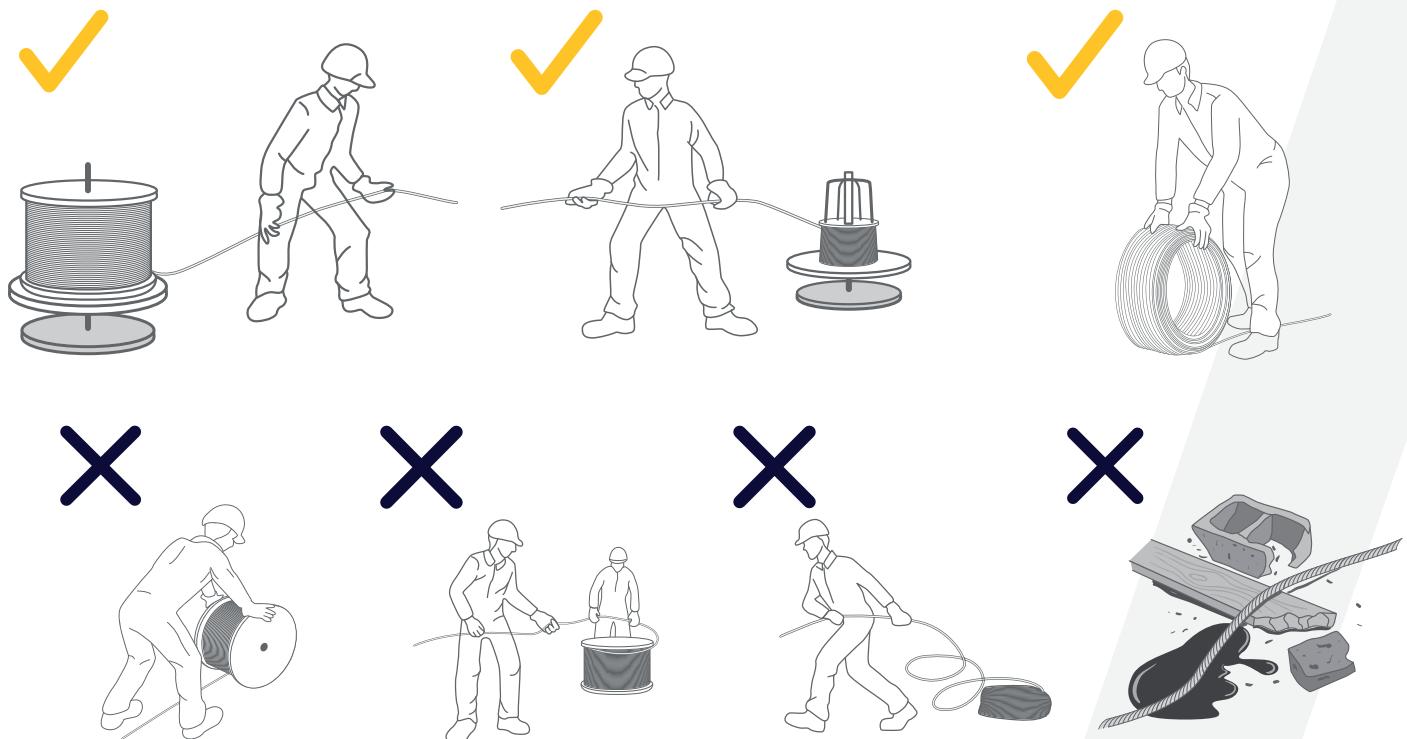

7. During unreeling, the alternating bending of the rope is not allowed. Unreeling from a wooden drum and reeling onto the winch drum (the bypass mechanism drum) should be done from bottom to bottom. In some cases, it is allowed to rewind from top to the top.

8. Releasing the outer end of the rope on a transport drum or on a coil should be carried out with extreme caution to avoid injury.

9. It is strictly forbidden to unreel the rope from the drum by dropping the wraps and then laying them into coils.

10. It is forbidden to stretch the rope on the ground before mounting it in order to measure the length or for other purpose. Length measurement should only be carried out on unreeling devices equipped with verified length counters.

Cutting off the rope

1. When cutting a rope (for measured lengths, for testing etc.), bandages (rope seizing) of soft wire should be applied on both sides of the cut. The number and width of the bandages, depending on the diameter of the rope, must correspond to the values shown in table. The distance between the bandages must be at least one lay length.

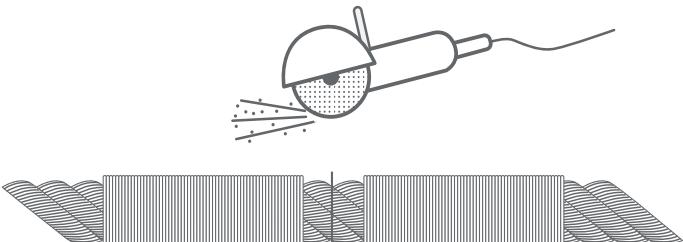

Parameters of the bandages (seizing)

Rope diameter, mm	Number of bandages for the rope, the least		Width of seizing, mm, the least
	Ordinary lay	Lang lay	
Up to 14.5	1*	1*	10
15.0-24.5	3	3	25
25.0-30.5	3	4	40
31.0-44.5	3	4	50
45.0-50.5	3	4	75
More than 51.0 **	3	4	100

* or the end of the rope should be welded up.

** the ends of ropes with a metal core with diameter that exceeds 57.0 mm should be welded up.

2. When cutting spiral supporting ropes, closed-type hoisting ropes, as well as multilayer stranded ropes at each end of the rope, it is necessary to install two four-bolt clamps rotated relative to each other by 90°, with a distance between them equal to 2 to 4 rope diameters. Instead of two four-bolt clamps, you can install eight two-bolt clamps close to each other, with a width of each clamp equal to the diameter of the rope.

Before removing the clamps, the ends of the rope should be securely welded up.

3. It is forbidden to cut ropes using electric welding.

4. Lack of proper ties on the rope when cutting can lead to deformation of the rope.

Rope installation

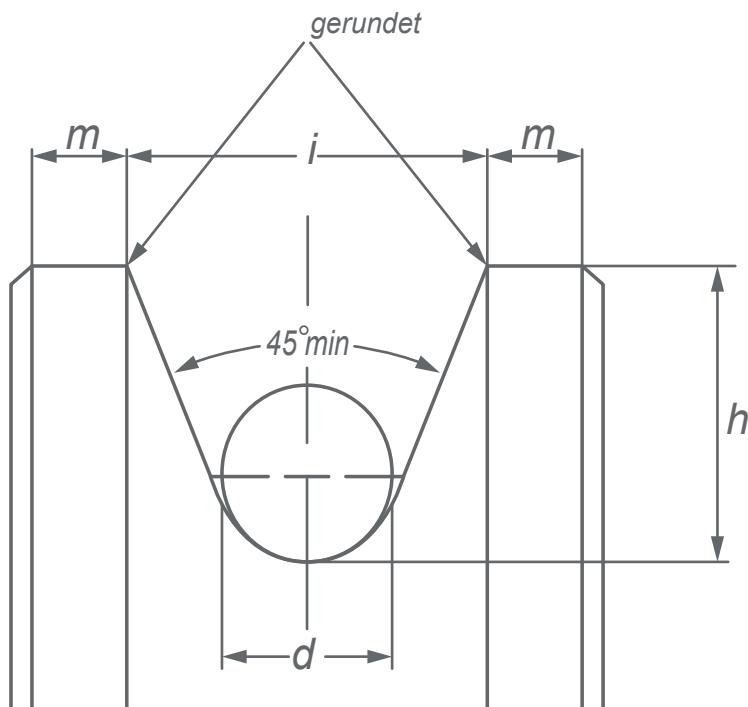

- After transporting the rope to the work place, it must be inspected for damage.
- Before installing a new rope, it is necessary to check the condition and parameters of the elements of the machine, equipment or device interacting with the rope, for example, drums, sheaves, guide rollers, etc. for the fact that they are within the recommended limits.
- Special attention should be paid to the parameters and condition of the pulley grooves of the system and pulley grooves of the drums of the corresponding winch. The diameter of the pulley groove should be 7.5% larger than the nominal diameter of the rope. Its control is carried out by means of special control gauges.

4. It is forbidden to use ropes with traces of wear, violation of the surface smoothness or mismatch of the parameters of the grooves of the pulleys, blocks and drums.

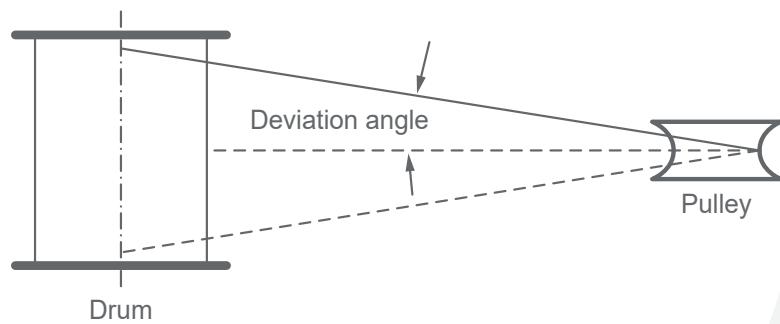

5. Too narrow pulley grooves will pinch and deform the rope, violating its structural integrity, which can lead to premature rope breakdown. Too large pulley grooves will create insufficient support, which will lead to increase in contact pressure and premature destruction of the rope wires.

6. The pitch of grooving on the winch drum should correspond to 1.15 dr - for ropes with a diameter of up to 10 mm, 1.12 dr - for ropes with a diameter of up to 20 mm and 1.11 dr - for ropes with a diameter of more than 20 mm (dr - diameter of the rope). Under any circumstances the actual diameter of the rope should be greater than the pitch of grooving on the equipment drum.

7. The opening angle between the sides of the groove should be within 45 to 60°. The opening angle of 30 to 45 ° is allowed at deviation angles less than 1° only.

8. The deviation angles when reeling the rope onto the drum should be within 0.5° to 2.5°. It is necessary to limit the deviation angle to 2.5° for the drums with grooving and to 1.5° for smooth drums. When using non-rotating, rotation-resistant ropes and parallel-closed ropes (i.e., ropes in which strands and cores are twisted into a rope in one operation), the deviation angle should be limited to 1.5°.

9. All sheaves must be well-balanced. The sheave support must maintain its straight position. The propelling sheave must be aligned with the center of the lifting drum. To ensure the turning force and smooth rotation, all sheaves must be properly lubricated.

10. The diameter and number of sheaves in the system affect the operating time of the rope. The lifespan of ropes working on sheaves and winches majorly depends on correctly chosen rope dimensions and a correct ratio of the winch drum diameter to the rope diameter D_d / d_r . Standards for various operating conditions for ropes usually indicate the minimum allowable values of D_d / d_r .

Recommendations for selection of diameters of the winch drum and grooves for universal steel ropes of various constructions (D_d / d_r)

Construction in acc. with EN and a whole construction		Analogue in GOST	Type of the rope	Recommended	Minimum allowed
6x19W-FC	6x19(1-6-6+6)-FC	2688-80	W	32	27

6x37M- WSC	6x37(1-6/12/18)-1x37(1-6/12/18)	3068-88	M	40	34

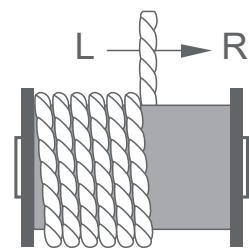

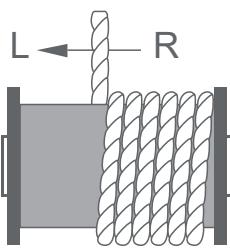

11. For mining ropes, the coefficients D_d/dr are completely different than for other applications and they are regulated by the relevant standards.

12. Such factor as speed may require increased D_d/dr ratio. For some applications lower than recommended D_d/dr is allowed, but in this case decreased lifespan of rope should be expected.

13. On winches with a single-lay spooling onto the drum, a spiral grooving is recommended. In case of multi-layered spooling, it is recommended to use drums with Lebus grooving.

14. Depending on the direction of the rope laying and the direction of its spooling onto the drum, the torsion deformation in the rope may decrease or increase. It is necessary to select the rope so that during the reeling process the rope is additionally twisted up. Under this condition, the density of laying and the associated service life of the rope will be increased. The direction of lay is of particular importance for smooth drums. The choice of the correct lay direction is absolutely necessary for the proper functioning of the reeving system. The use of a left-lay rope, when a right-lay rope should be used (and vice versa), will increase the torque, which will lead to the problems during reeling and structural damage to the rope. The direction of rope reeling and direction of the winch drum rotation must be taken into account in accordance with Table 3, unless otherwise specified in the original instructions of the equipment manufacturer.

Choice of the place and direction of rope reeling onto the drum

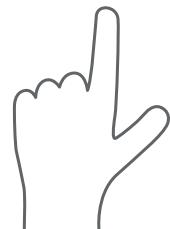

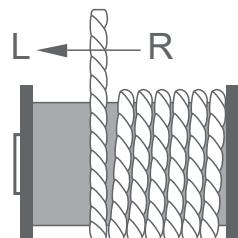

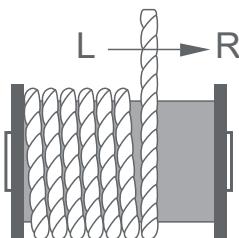

Beginning of rope reeling from the right side of the drum for the right-lay rope

Right-lay rope – reeling from the bottom of the drum

Beginning of rope reeling from the left side of the drum for the left-lay rope

Left-lay rope – reeling from the bottom of the drum

Beginning of rope reeling from the left side of the drum for the right-lay rope

Right-lay rope – reeling on the top of the drum

Beginning of rope reeling from the right side of the drum for the left-lay rope

Left-lay rope – reeling from the top of the drum

The index finger indicates the direction of rope reeling off the drum

Beginning of rope reeling from the left side of the drum for the right-lay rope

The thumb points at the place of rope attachment to the drum

The right or left hand points at the desired direction of rope laying

The rope is reeled from the bottom

The rope is reeled from the top

15. Ropes should be reeled onto the winch drum evenly. The first row of the rope should be reeled onto the drum very tightly, without overlapping and intersection of the subsequent layers, so that the rope will be not damaged during operation.

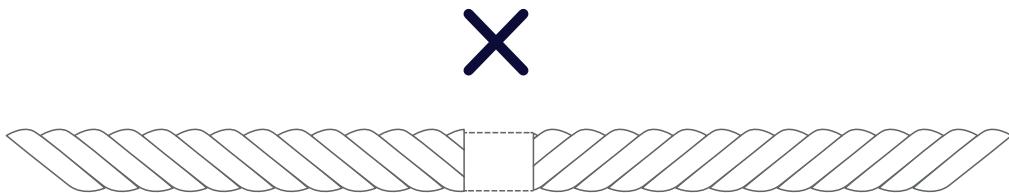

16. As practice shows, the constructions of certain hoisting machines may not be able to meet all recommended requirements, which will reduce the service life of the rope. In this case, it is necessary to inspect the rope more often.

17. The rope can be installed by reeling it onto the drum of the hoisting machine directly from the factory reel or from special winches (winches with a drive and brake, which serve to perform the main work on rope suspending), on which the rope has been re-spooled from the factory reel before.

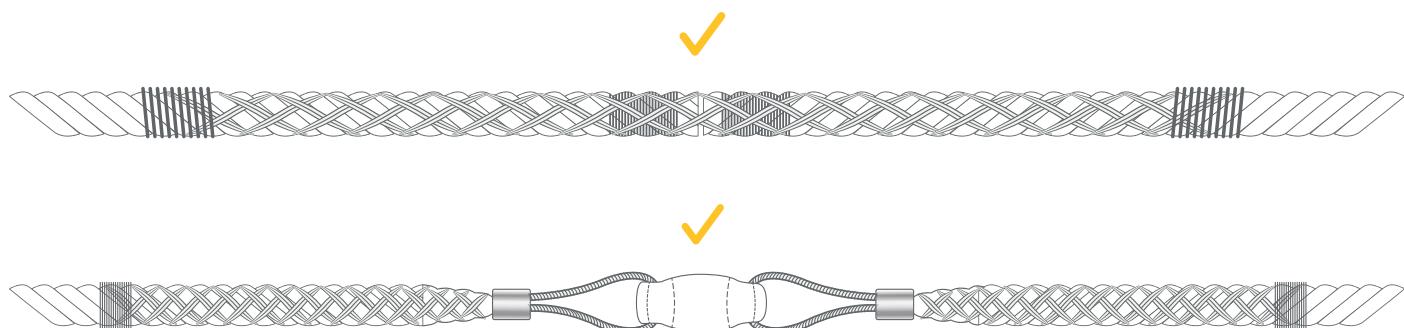

18. A drum shaft with a rope weight of more than five tons is preferably to be installed with rolling bearings, which will significantly simplify the re-spooling process.

19. The transport drum with a rope should be placed as far from the winch drum or the guide roller as possible in order to minimize any influence of the deviation angle, which will prevent from any undesirable effects due to the torsion of the rope.

20. When new rope is being mounted, it is not allowed to connect the old and new ropes having different lay direction. The connection of ropes with different lay direction will lead to rotation of the rope and to the unwinding of the strands when loading the rope.

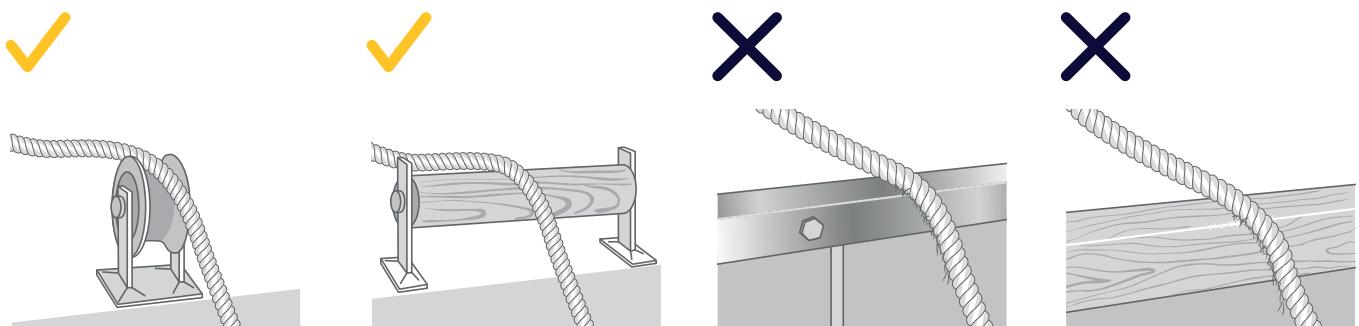

21. For installation of a new rope by means of an old rope, it is recommended to use rope grippers – “mesh grip”. The open end of the “grip” should be securely attached to the rope with a bandage or alternatively with a suitable clamp.

22. It is allowed to connect the ends of the old and new ropes with a piece of rope made of organic materials of sufficient strength in order to prevent rotation transmitted from the old rope to the new one. If a wire rope is used, it must be a type of a rope that resists to rotation, or such a rope must be of the same type and have the same direction of lay, as the new rope has. If the rope was twisted when installing, this may lead to its damage or to rotation of the hook cage.

23. Extremely precise observance of the rules should be taken, when working with ropes with metal core. Moreover, a special attention should be paid to the ropes of parallel and lang lay while being mounted, as they are more prone to untwisting.

24. While mounting the rope, the swivel should not be used.
25. Before mounting the rope into the system, make sure that there are no obstacles in its way in the form of structures or mechanisms that can damage the rope.

26. In the process of reeling, carefully check for rope tension.
27. During installation of the rope, all of its operating parameters and characteristics specified by the manufacturer must be maintained.
28. The rope should be attached to the drum in such a way that when passing through the hole in the cylinder of the drum it is not deformed by the sharp edges of the hole. Fastening of the ends of the rope is made at specifically designed places on the drum, which make it possible to fix the rope in at least three points.
29. When inserting the free end of the rope into the shaft of the mine for connecting to the hoisting conveyance or to the back-weight, a guide frame must be used in order to prevent rope rotation under its own weight. During rope installation, ensure that the wire-line running end of the rope is fixed against rotation around its axis.

Operation

- Proper reeling, installation and handling of a steel rope significantly prolongs its service life. Maintenance, replacement, cutting, and installation of the rope should be carried out under supervision of a competent employee of the enterprise, in accordance with the prescribed labor safety measures, instructions of the equipment manufacturer and supervisory authorities.
- Double lay ropes with fibre cores or organic cores may be used at temperature of up to 100° C. Double-lay ropes with metal cores and regular-lay ropes may be used at temperature up to 200° C, while some reduction in the minimum breaking load is necessary, the value of which depends on the time of exposure to high temperature and on the diameter of wires. At operating temperatures between 100° C and 200° C, the loss in strength is about 10%. At temperatures between 200° C and 300° C - 25%, between 300° C and 400° C - 35%. Therefore, if necessary, you should consult with the producer of the rope.
- Rope operation at low temperatures (less than -40° C) will not adversely affect the strength of steel wire ropes, therefore there is no need to reduce the minimum breaking load. However, depending on the effectiveness of rope lubrication, at low temperatures the strength characteristics of the rope may be reduced. When operating at temperatures below -40° C and above 80° C, special rope lubricants should be used.
- Since in the initial period of operation there is a constructive lengthening of the rope and redistribution of stresses in the rope, it is necessary to trial run it in and tighten it. Trial-run and tightening of the rope should be done with a gradual increase in load and speed. This will ensure the gradual stabilization of internal stresses in the rope and allow it to be adapted to the working conditions.

5. The following rope running mode is recommended: at least 5 cycles (the cycle includes rope reeling on the winch drum and its subsequent unreeling) without a load, 5 cycles at a load of 10% of the maximum force during operation, 5 cycles at a load of 20-30%, 5 cycles with a load of 50%, then 5 cycles with a maximum load, and finally reel the rope onto the drum with a force of about 10%. Repeating the cycles with each load is performed with a gradual increase in speed from minimum to nominal one.

6. It is forbidden to trial-run and tighten ropes with a maximum load, or even more - with an overload.

7. After installing, trial-run and tightening the ropes, it is necessary to inspect the ropes and securing points, only if there are no abnormalities, it is allowed to carry out their operation in the normal mode.

8. In the process of rope operation, it is necessary to inspect the condition of sheaves, blocks, drums. For normal rotation, they must be fault-free and lubricated. Do not allow rope friction against the structural elements, soil, etc. To avoid damage to the rope, where necessary, installation of supporting or deflecting rollers is required.

9. In case of multilayered winding onto the drum, it is recommended to use ropes with metal cores and compacted strands, which are more resistant to crushing and deformation.

10. In order to reduce rope wear in certain areas and, hence, to prolong service life of the rope, we recommend to shorten the rope after operation for a definite period of time by cutting off a piece from the end attached to the winch drum. Thus, the most worn rope sections will be shifted, giving way to undamaged rope sections. The trimming operation of ropes intended for severe operating conditions should be carried out with a certain frequency, without waiting for the complete abrasion of the rope.

11. In case of multi-layered reeling of the rope onto the drum, it is recommended to use its full length (excluding friction coils). If it is intended to use only a certain part of the rope for a long time, then it should be replaced with a shorter one.

12. During operation, slackening and lapping of the rope should be avoided.

13. Avoid actions that cause transverse swaying of the rope during operation.

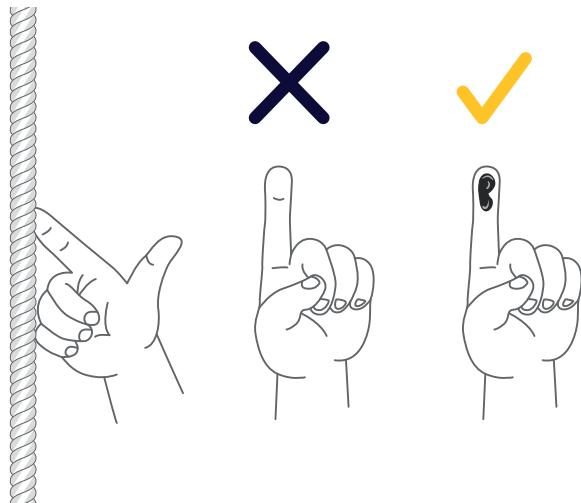

Lubrication of the rope

1. To protect ropes from corrosion and abrasive wear during operation, it is necessary to regularly lubricate their surfaces with rope lubricants approved for use in the established procedure, only after having previously cleaned the rope of old grease and dirt. It is forbidden to use solvents and other cleaning substances.

2. The ropes service lubricant must be compatible with the original factory one. Impure or used greases are not allowed for use. The type and method of lubricant applying should ensure a uniform covering of all wires of the rope with a thin layer.

3. The frequency of lubrication should be selected on the base of specific operating conditions and maintenance of the integrity of the lubricating layer on the rope surface (and for mine ropes - at least once a month).

4. When inspecting ropes under a pitcher, clamps, etc. these places of the ropes should also be lubricated.

5. When using "dry" cables, the intervals between inspections should be reduced. The performance of a "dry" rope, subjected to bending fatigue (but without corrosion), often reaches only 30% of the performance of a lubricated rope.

Rope inspection and its rejection

1. The condition of the rope and the hoisting equipment shall be checked before the start of each work shift. Especially thorough checks shall be performed after abnormal situations that could cause damage to the rope or equipment.

2. The rope is to be checked along its entire length, with special attention paid to those sections that are the main potential areas of damage. Excessive wear, broken wires, deformation and corrosion are common signs of damage.

3. If the ropes work on drums or sheaves, special attention should be paid to inspection of areas of entry or exit from the troughs under maximum loads and areas that for a long time remain under the effect of the environment, for example, in the area of hoisting sheaves.

4. The intervals for carrying out inspection and due surveying, as well as the criteria for rejection, should meet the requirements of the following standards (unless any other standard or regulatory document is applied):

- Steel wire ropes for cranes - ISO 4309;
- Steel wire ropes for mining - ISO 4309 or BS 6570;
- Steel wire ropes for elevators - ISO / FDIS 4344;
- Steel wire ropes for aerial cableways - prEN 12927-7;
- Steel wire ropes for the oil and gas industry - API RP54, API RP 9B.

5. Detailed information on the maintenance, inspection, and rejection of steel ropes can be found in the listed European standards, as well as in the standards established by the regulatory and supervisory authorities of countries in which ropes are used.

6. To estimate safety of further rope operation, the following criteria are used:

- a) the nature and number of broken wires, including presence of broken wires at the terminations, presence of broken wire concentration points, intensity of increasing in broken wires number;
- b) strand break;
- c) surface and internal wear;
- d) surface and internal corrosion;
- e) local reduction of the rope diameter, including break of the core;
- f) reduction of the cross-sectional area of wires of rope;
- g) deformation in the form of waviness, basket shape, extrusion of wires and strands, crushing of strands, bends, kinks, etc.;
- h) damage as a result of temperature effects or electric arc discharge.

7. During visual inspection the steel rope shall not have visible defects. Special attention during the inspection shall be paid to the fact that the ropes have no knots and loops, buckling strands or twisting, torn strands and individual wires, signs of surface wear.

8. Presence of a gap between the strands in the ropes with a metal core, protruding fluff of the fiber core between the strands in the ropes with a fiber core, as well as presence of one or several galvanized wires in the ropes without coating, are not the grounds the for rope rejection. Ropes with a fibre core may have gaps between the strands, thereby the diameter of the rope must not exceed the indicated maximum deviations.

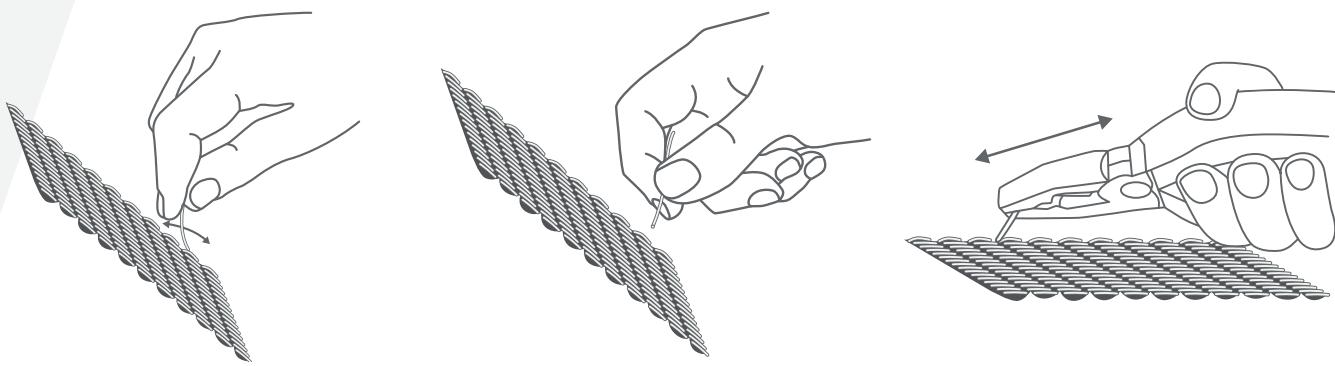

9. Rejection of steel ropes in operation is made according to the number of broken wires at a certain length.

10. Wire breakage is a normal occurrence in rope operation, especially common at the end of its service life as a result of wear and bending fatigue. While local wire breakage may indicate mechanical failure of the equipment.

11. Before inspection, the rope should be cleaned of old grease, dirt and wear products. On examination, rope sections with the largest number of broken wires are to be found. Usually, these are the rope segments that undergo the largest number of kinks on the blocks and are reeled onto the drum. It is on these sections of the rope that it is necessary to determine the absolute number of broken wires.

12. The number of broken wires is determined visually or by means of detectoscopy. For the convenience of visual counting of the number of broken wires, the rope should be slightly bent. Thereby, the number of wire breaks should not be confused with the number of ends of broken wires, which is always twice as large.

13. The ends of the broken wires must always be removed from the rope, by their reverse bending with pliers until the wires break deep in the gap between the two outer strands. It is not allowed to leave the broken wires, as they will cause destruction of the neighboring wires, in the process of loaded rope repeatedly running through the blocks.

14. The number and location of the removed ends of the broken wires should be recorded in the log for their subsequent consideration when rejecting the rope according to the criterion of broken wires.

15. Steel ropes, in which the number of wire breaks at a specified length did not reach the rate of rejection or having acceptable surface wear of wires, may be allowed for further operation subject to careful observance of their condition, increasing of frequency of inspections and making appropriate records in the crane log. As soon as norms of rejection are fulfilled, these ropes are subject to rejection and replacement.

Other requirements

1. Any other requirements for steel rope operation, the presence of which are not obligatory, are established by the operating organization depending on the type of hoisting mechanism, operating conditions and requirements of the European standards, as well as the standards established by the regulatory and supervisory authorities, internal regulations that do not contradict these regulations, approved in the prescribed procedure by the operating organization.

2. All warranties of quality, performance, or suitability of a steel rope for use, whether expressed or implied, always assume that the specified strength values apply only to a new, unused rope, that this rope is used on nonfaulty equipment of a relevant design, that storage, handling, use, maintenance of ropes are made in accordance with the established requirements, with regular inspections during their operation.

3. The seller shall under no circumstances be liable for consequential or incidental damages, or for subsequent claims, including but not limited to injuries, labor costs or loss of profits arising from the use of these products, or inclusion of these products as a component to any other products.

Mining lifting ropes intended for vertical shafts with depth of more than 800 m, equipped with winders drum-type, can have a variable lay step in different sites along the length of the steel wire rope.

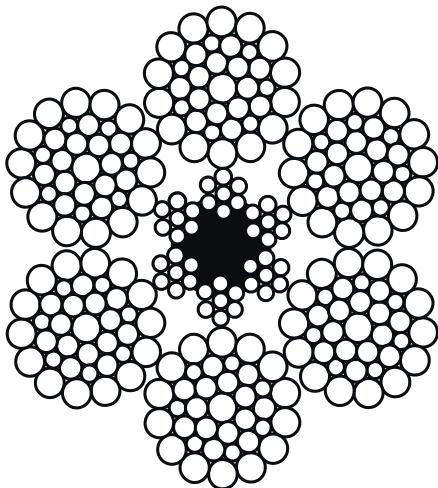

The manufacturer defines the value of lay steps at various sites along the length of the steel wire rope in accordance with customer requirements.

Mining lifting ropes variant "B" intended for vertical shafts with depth of more than 800 m, equipped with winders drum-type, can have a variable lay step in different sites along the length of the steel wire rope.

The manufacturer defines the value of lay steps at various sites along the length of the steel wire rope in accordance with customer requirements.

Rope can be produced in three types of execution:

- execution “U” – with constant lay step for all types hoisting plants;
- execution “B” – with variable lay step for drum type hoisting plants;
- execution “SH” – with variable lay step for hoisting plants with friction pulleys.

Mining lifting ropes for vertical shafts with depth of more than 800 m, equipped with winders drum-type, can have a variable step of laying in different sites along their length.

The manufacturer defines the value of laying steps at various sites along the length of the steel wire rope as agreed with the customer in accordance to requirements to the operation of that steel wire rope.

Mining lifting ropes variant "B" intended for vertical shafts with depth of more than 800 m, equipped with winders drum-type, can have a variable lay step in different sites along the length of the steel wire rope.

The manufacturer defines the value of lay steps at various sites along the length of the steel wire rope in accordance with customer requirements.
